3-Phase Hybrid Stepping Motor Driver

HIGH TORQUE, SILENT ROTATION

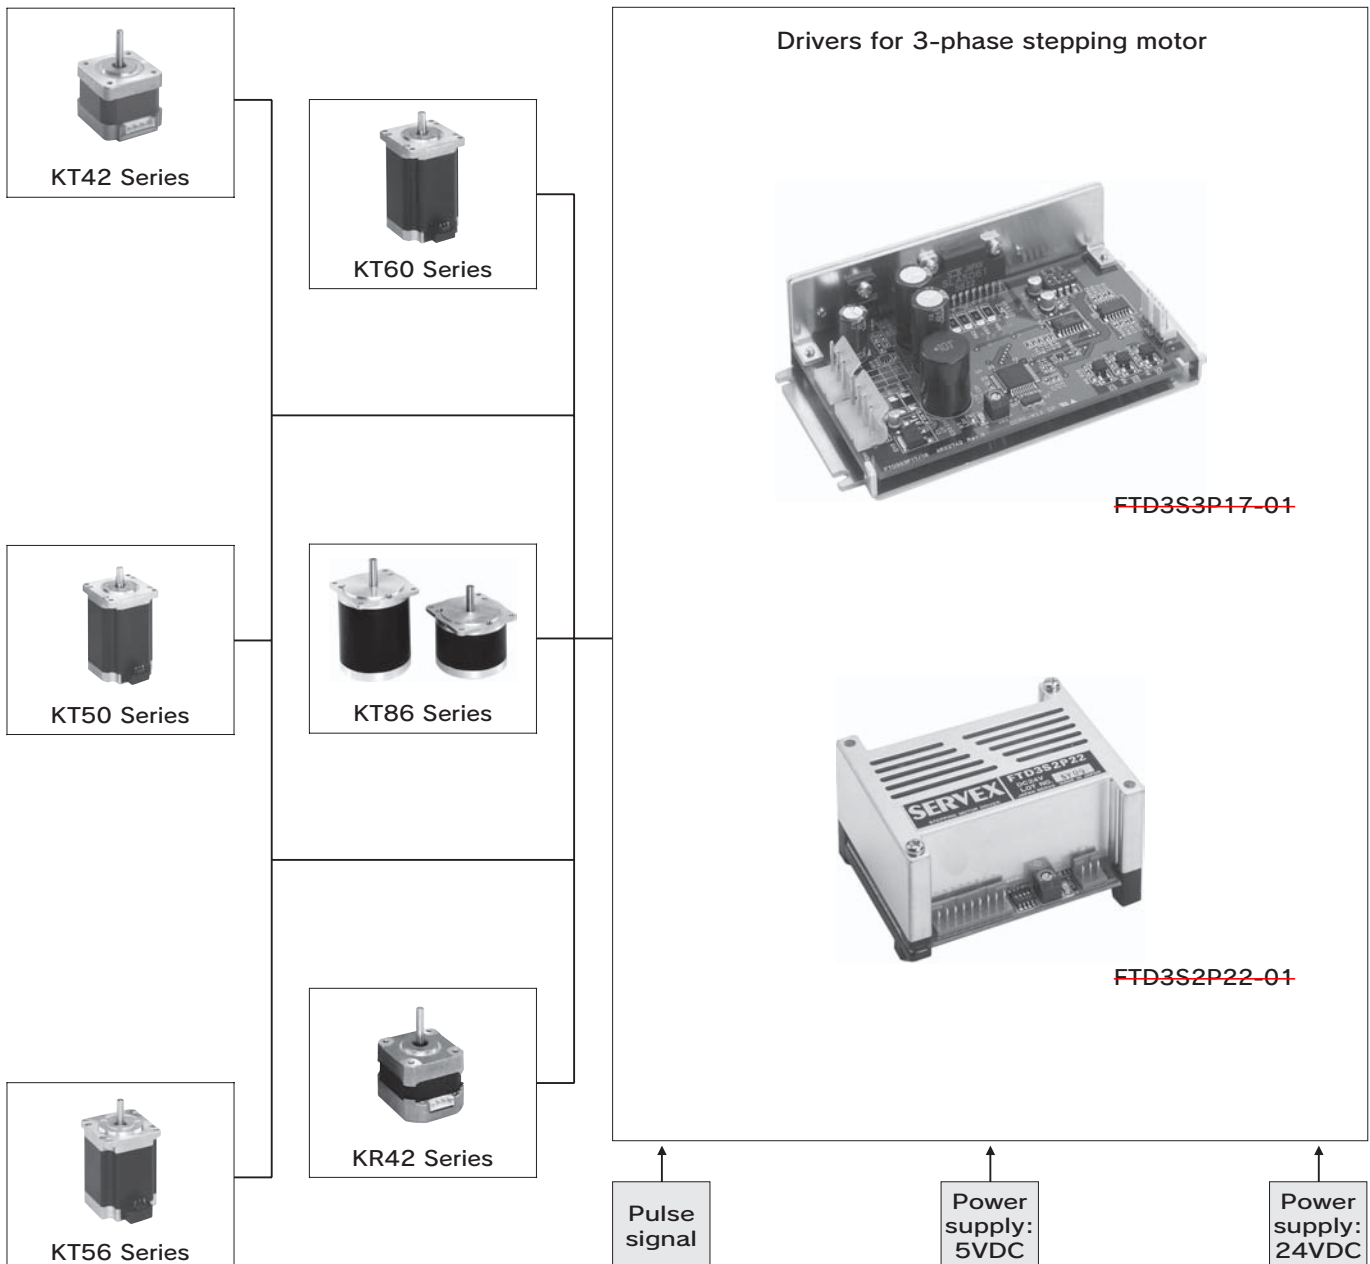

Features

1. Drive circuit is simplified because the motor is driven with star wiring connection.
2. High torque is obtained at low speed with the micro-step driver.
3. Ultra-low vibration and low noise achieved with our micro-step driver.
4. The step angle of 1/1, 1/2, 1/4, and 1/8 may be chosen using our micro-step driver.

Applications

Suitable as controlled driving source in scientific or high precision industrial equipment such as OA equipment, measuring equipment, medical treatment equipment, physics and chemistry equipment, optical equipment, semiconductor processing equipment, and other precision machinery.

System Configuration

Vibration Comparison

Advantage

Constant current driver

With the fixed current drive method, a voltage sufficiently higher than the specified voltage, of the motor, is finely sliced in the switching circuit than applied to the motor coil. The current is maintained at a constant level whether the motor is rotating at low or high speed. With this method the output torque during high speed rotation is greatly improved with power consumption minimized.

Micro-step driver

With the micro-step drive method, the mechanically determined step angle (3.75° , 1.2° or 0.60°) is divided by an electronic circuit and the motor is gradually rotated by a fine angle. The conventional excitation method makes a rotor rotates by a fixed angle by turning the magnetizing phase on and off through an input pulse. On the other hand, with the micro-step driving method, the current of one phase of the magnetizing phase can be gradually increased while the current of other phase is decreased thereby further dividing the step angle of the motor and making rotation even smoother.

THE FTD3S3P17 driver, the FTD3S2P22 enable to set to step divisions of 1/4 and 1/8. Micro stepping drive is effective to reduce mechanical driving noise particularly when divisions not exceeding 1/8.

Rectangular wave drive

- 2-phase excitation (full-step)

This is then or mal 2-phase excitation method. Torque is large and damping characteristics are excellent.

	Noise level	Vibration	Torque		High speed capability
			Low speed	High speed	
Micro-step drive	○	○	○	△	△
Rectangular wave drive	△	△	○	○	○

Explanation of the Dynamic Torque Curve

Self-starting region

This is the region in which motors can be started and stopped instantaneously.

Pulse rate

The number of pulses in a unit of time, and is shown in the unit "pps" which means "pulses per second". The relation between pulse rate, speed (rpm) and angular velocity (rad/s) is given below.

$$\omega = \frac{\pi}{180} \theta_s \cdot P \rightarrow P = \frac{180}{\pi} \cdot \frac{\omega}{\theta_s}$$

$$N = \frac{1}{6} \theta_s \cdot P \rightarrow P = \frac{6N}{\theta_s}$$

where ω : Angular velocity (rad/s)
 θ_s : Step angle (deg.)
 N : Speed (rpm)
 P : Driving pulse rate (pps)

Maximum self-starting frequency (pps)

This is the maximum pulse rate in the self-starting region. Care must be taken, because it varies depending on the load inertia.

Slew region

In this region, driving is possible only by slow acceleration/slow deceleration control.

Maximum response frequency (pps)

This is the maximum pulse rate in the slew region.

Pull-in torque

This is the torque generated when started in the self-starting region. It is also called the "synchronization torque".

Pull-out torque

This is the torque generated when driven in the slew region.

Pull-out

This means the motor is coming out of synchronized operation by being not able to follow the pulse signal from the pulse generator.

Over-loading is the general cause, but noise (Electric/ Electro-magnetic) is also a cause in some cases.

Slow acceleration/slow deceleration

This is a kind of control to raise or lower the pulse rate to drive stepping motors in the slew region so they exhibit their full capability. There are various methods but one example, called trapezoidal driving, is shown in Fig. 2.

Resonance phenomenon

When stepping motors are driven, torque decrease, miss-steps, vibration and other unfavorable phenomena may occur at some specific frequencies. This is called a "Resonance phenomenon", and is caused by the coincidence of intrinsic vibration frequency and input pulse frequency of the motor. It is experienced generally in the range of 100 to 200 pps. It is impossible to eliminate this resonance fully, but the defect can be reduced by changing the excitation mode or providing damper.
